def output_to_date(out, vocab):
    # this time the "vocab" is index_word
    arr = np.argmax(out,axis=-1)
    string = ''
    for i in arr:
```

```
        string += vocab[i]

    return string
```

[74]:
```
X = []

for content in contents:
    X.append(string_to_onehot(
        content,
        MAX_SEQ_LENGTH,
        agent_data_char_vocab_word_index)[0]
    )
```

0.0.4 Split our dataset into training ones and testing/validation ones.

The validation dataset is used to test whether or not our prediction model can "generalize" to data that the model has never seen. It can happen that our trained model performs very well on training dataset but works poorly to new data. This phenomenon is called **over-fitting**.

[75]:
```
X_train, X_test, Y_train, Y_test = train_test_split(X, labels, test_size=0.2)

X_train = np.array(X_train)
X_test = np.array(X_test)
Y_train = np.array(Y_train)
Y_test = np.array(Y_test)
```

[76]:
```
labelBinarizer = LabelBinarizer()
labelBinarizer.fit_transform(labels)
Y_train = labelBinarizer.transform(Y_train)
Y_test = labelBinarizer.transform(Y_test)
```

[77]:
```
print(Y_train[0].shape)
```

```
(56,)
```

0.0.5 Example of Transformed Training data that will be fed into LSTM Model

[218]:
```
X_train[0]
```

[218]:
```
array([[0., 0., 0., …, 0., 0., 0.],
       [0., 0., 1., …, 0., 0., 0.],
       [0., 0., 0., …, 0., 0., 0.],
       …,
       [0., 0., 0., …, 0., 0., 0.],
       [0., 0., 0., …, 0., 0., 0.],
       [0., 0., 0., …, 0., 0., 0.]])
```

0.0.6 Define Model

Based on the size of training data and after numerical experiement, we finally come up with the following structure. In case when we have more and more data in the future, we need to adjust the retrain the model in order to accept more information.

[78]:
```
def build_model():
    inputs = Input(name='inputs',␣
 ↪shape=(MAX_SEQ_LENGTH,len(agent_data_char_vocab_word_index)))
    x = LSTM(128)(inputs)
    x = Dense(256,name='FC1')(x)
    x = Activation('tanh')(x)
    x = Dense(128,name='FC2')(x)
    x = Activation('relu')(x)
    x = BatchNormalization()(x)
    x = Dropout(0.5)(x)

    x = Dense(NUM_CLASSES, name='out_layer')(x)
    x = Activation('softmax')(x)
    model = Model(inputs=inputs, outputs=x)
    return model

model = build_model()
```

0.0.7 Check the Shape of data Before Training

[79]:
```
print(X_train.shape)
print(Y_train.shape)
print(X_test.shape)
print(Y_test.shape)
```

```
(1028, 40, 39)
(1028, 56)
(258, 40, 39)
(258, 56)
```

0.0.8 Compile the model

[80]:
```
model.compile(
    loss='categorical_crossentropy',
    optimizer=Adam(lr=INIT_LR),
    metrics=['acc']
)
```

0.0.9 Define learning rate scheduler

[81]:
```
def poly_decay(epoch):
    if epoch < 30:
        return INIT_LR
    elif epoch in range(30, 60):
        return INIT_LR * 0.1
```

[82]:
```
lr_scheduler = tf.keras.callbacks.LearningRateScheduler(poly_decay)
```

0.0.10 Train the model

[83]:
```
%matplotlib inline
import matplotlib.pyplot as plt

history = model.fit(
    X_train,
    Y_train,
    validation_data = (X_test, Y_test),
    batch_size=64,
    epochs=60,
    callbacks=[lr_scheduler]
)

epoch_list = history.epoch

plt.plot(epoch_list, history.history['loss'], label='Train Loss')
plt.plot(epoch_list, history.history['val_loss'], label='Validation Loss')

plt.ylabel('Loss')
plt.xlabel('Epoch');plt.title('Loss')

plt.legend(loc="best")
plt.grid(color='gray', linestyle='-', linewidth=0.5)
```

```
